Introduction

This project focuses on the development of an Augmented Reality (AR) application designed for a digital museum experience.

The main goal is to give user additional information about artworks.

When a user scans a painting, the application recognizes the image and displays related informational content.

demo

Poppy Field

Coquelicots - Oil on canvas

1873 · Argenteuil, France · Claude Monet

A sun-drenched field of scarlet poppies near Argenteuil, painted during Monet's most fertile Impressionist period. Loose, rapid brushstrokes and natural light capture a fleeting moment of rural tranquility.

Fun fact: Poppy Field was one of the works that gave Impressionism its name, exhibited at the landmark 1874 show that initially shocked critics and the public.

Implementation

The application was developed using Vuforia.

Vuforia implements Image Targets, which allow us to define images of interest that the system can recognize.

Once the image target is detected, tracking is initiated, and the child objects attached to the Image Target are displayed and positioned relative to it.

In this case, a plane containing additional information about the artwork is shown when the target image is recognized.
